

# Heap

06 May 2026 18:37

What is heap memory?

In Java, the heap is a runtime memory area where:

- Objects are created using **new** keyword
- Instance variables are stored
- Managed by Garbage Collection(gc)

## Features of Heap memory

- Shared among threads
- Dynamically allocated
- Automatically managed
- Garbage Collector removes unused objects.

## Heap Data Structure

What is heap?

A heap is a complete binary tree that satisfies the heap property.

Types:

1. Max heap---> parent node  $\geq$  child node
2. Min heap---> parent node  $\leq$  child node

A heap is a complete binary tree(CBT).

What is complete binary tree?

A complete binary tree is a specific type of binary tree with strict structural property.

Definition:

A complete binary tree :

- a. All levels are completely filled except possibly the last level.
- b. The last level is filled from left to right without gaps.

Properties:

1. Nodes are filled level by level.
2. Last level nodes are left as possible.
3. No "gaps" between nodes.

$$2^{3+1} - 1 = 2^4 - 1 = 16 - 1 = 15$$

1. Nodes are filled level by level.

2. Last level nodes are left as possible.

3. No "gaps" between nodes.

What is the relation with array representation?

$$\left. \begin{aligned} \text{parent} &= (i-1) / 2 \\ \text{left child} &= 2 \times i + 1 \\ \text{right child} &= 2 \times i + 2 \end{aligned} \right\} \text{By using this relationship, we can fetch our required information.}$$

Why complete binary tree is important?

It represents:

- Heap data structure
- Heap sort
- Priority Queue
- Efficient storage(array-based)
- No gaps -> predictable indexing

Height Property: For a complete binary tree with N nodes:

$$\text{Height} = \lfloor \log_2(n) \rfloor$$

### Heap Sort

Heap sort is a comparison based sorting algorithm that:

- Builds a Max heap
- Repeatedly extracts the maximum element
- Place it at the end

To sort an array using heap

- Convert array into max heap.
- Swap root (largest) with last element.
- Reduce the heap size.
- Heapify again.
- Repeat

### Core Idea

Heapify assumes:

- Left and right are already heaps
- Only the current node may violate the heap property
- So we push down the element to its correct position.

### Algorithm

- Assume current node is largest.
- Compare with left child.
- Compare with right child.
- Swap with largest if needed.
- Recursively heapify affected subtree.

```

public static void heapify(int a[], int n, int i){
    int largest = i;
    int left = 2*i + 1;
    int right = 2*i + 2;
    if(left < n && a[left] > a[largest]){
        largest = left;
    }
    if(right < n && a[right] > a[largest]){
        largest = right;
    }
    if(largest != i){
        int t = a[i];
        a[i] = a[largest];
        a[largest] = t;
        heapify(a, n, largest);
    }
}

public void sort(int a[]){
    int n = a.length;
    //step 1: Builds a Max heap
    for(int i = n/2 - 1; i > -1; i--){
        heapify(a, n, i);
    }
    //step 2: Repeatedly extracts the maximum element
    for(int i = n - 1; i > 0; i--){
        int t = a[0];
        a[0] = a[i];
        a[i] = t;
        heapify(a, i, 0);
    }
}

```

$n = 6$   
 $i = 2$   
 $left = 5$   
 $right = 6$   
 $t = 7$

$n = 4$   
 $i = 0$   
 $left = 1$   
 $right = 2$   
 $t = 6$

$a \rightarrow$ 

|   |   |   |    |    |    |
|---|---|---|----|----|----|
| 5 | 6 | 7 | 11 | 12 | 13 |
|---|---|---|----|----|----|

$n = 6$   
 $i = 2$   
 $t = 13$

Sort the array into descending order, and try to use generics in your code.
